Summary

MATLAB routines

For any BIBO stable filter,  $H(e^{j\omega})$  is the DTFT of  $h[n]$

$$H(e^{j\omega}) = \sum_{-\infty}^{\infty} h[n]e^{-j\omega n} \Leftrightarrow h[n] = \frac{1}{2\pi} \int_{-\pi}^{\pi} H(e^{j\omega})e^{j\omega n} d\omega$$

If we know  $H(e^{j\omega})$  exactly, the IDTFT gives the ideal  $h[n]$

**Example:** Ideal Lowpass filter

$$H(e^{j\omega}) = \begin{cases} 1 & |\omega| \leq \omega_0 \\ 0 & |\omega| > \omega_0 \end{cases} \Leftrightarrow h[n] = \frac{\sin \omega_0 n}{\pi n}$$

**Note:** Width in  $\omega$  is  $2\omega_0$ , width in  $n$  is  $\frac{2\pi}{\omega_0}$ : **product is  $4\pi$  always**

Sadly  $h[n]$  is **infinite** and **non-causal**. **Solution:** multiply  $h[n]$  by a window

# Rectangular window

## 6: Window Filter Design

### Inverse DTFT

#### ▷ Rectangular window

#### Dirichlet Kernel +

#### Window relationships

#### Common Windows

#### Order Estimation

#### Example Design

#### Frequency sampling

#### Summary

#### MATLAB routines

Truncate to  $\pm \frac{M}{2}$  to make finite;  $h_1[n]$  is now of length  $M + 1$

### MSE Optimality:

Define mean square error (MSE) in frequency domain

$$\begin{aligned} E &= \frac{1}{2\pi} \int_{-\pi}^{\pi} |H(e^{j\omega}) - H_1(e^{j\omega})|^2 d\omega \\ &= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left| H(e^{j\omega}) - \sum_{-\frac{M}{2}}^{\frac{M}{2}} h_1[n] e^{-j\omega n} \right|^2 d\omega \end{aligned}$$

Minimum  $E$  is when  $h_1[n] = h[n]$ .

**Proof:** From Parseval:  $E = \sum_{-\frac{M}{2}}^{\frac{M}{2}} |h[n] - h_1[n]|^2 + \sum_{|n| > \frac{M}{2}} |h[n]|^2$

**However:** 9% overshoot at a discontinuity even for large  $n$ .

Normal to delay by  $\frac{M}{2}$  to make causal. Multiplies  $H(e^{j\omega})$  by  $e^{-j\frac{M}{2}\omega}$ .

#### Frequency sampling

#### Summary

#### MATLAB routines

Truncation  $\Leftrightarrow$  Multiply  $h[n]$  by a rectangular window,  $w[n] = \delta_{-\frac{M}{2} \leq n \leq \frac{M}{2}}$

$\Leftrightarrow$  Circular Convolution  $H_{M+1}(e^{j\omega}) = \frac{1}{2\pi} H(e^{j\omega}) \circledast W(e^{j\omega})$

$$W(e^{j\omega}) = \sum_{-\frac{M}{2}}^{\frac{M}{2}} e^{-j\omega n} \stackrel{(i)}{=} 1 + 2 \sum_1^{0.5M} \cos(n\omega) \stackrel{(ii)}{=} \frac{\sin 0.5(M+1)\omega}{\sin 0.5\omega}$$

Proof: (i)  $e^{-j\omega(-n)} + e^{-j\omega(+n)} = 2 \cos(n\omega)$  (ii) Sum geom. progression

Effect: convolve ideal freq response with Dirichlet kernel (aliased sinc)

Provided that  $\frac{4\pi}{M+1} \ll 2\omega_0 \Leftrightarrow M+1 \gg \frac{2\pi}{\omega_0}$

Passband ripple:  $\Delta\omega \approx \frac{4\pi}{M+1}$ , stopband  $\frac{2\pi}{M+1}$

Transition pk-to-pk:  $\Delta\omega \approx \frac{4\pi}{M+1}$

Transition Gradient:  $\left. \frac{d|H|}{d\omega} \right|_{\omega=\omega_0} \approx \frac{M+1}{2\pi}$

# [Dirichlet Kernel]

## Other properties of $W(e^{j\omega})$ :

The DTFT of a symmetric rectangular window of length  $M + 1$  is  $W(e^{j\omega}) = \sum_{-\frac{M}{2}}^{\frac{M}{2}} e^{-j\omega n} = e^{j\omega \frac{M}{2}} \sum_0^M e^{-j\omega n} = e^{j\omega \frac{M}{2}} \frac{1 - e^{-j\omega(M+1)}}{1 - e^{-j\omega}} = \frac{e^{j0.5\omega(M+1)} - e^{-j0.5\omega(M+1)}}{e^{j0.5\omega} - e^{-j0.5\omega}} = \frac{\sin 0.5(M+1)\omega}{\sin 0.5\omega}$ .

For small  $x$  we can approximate  $\sin x \approx x$ ; the error is  $< 1\%$  for  $x < 0.25$ . So, for  $\omega < 0.5$ , we have  $W(e^{j\omega}) \approx 2\omega^{-1} \sin 0.5(M+1)\omega$ .

The peak value is at  $\omega = 0$  and equals  $M + 1$ ; this means that the peak gradient of  $H_{M+1}(e^{j\omega})$  will be  $\frac{M+1}{2\pi}$ .

The minimum value of  $W(e^{j\omega})$  is approximately equal to the minimum of  $2\omega^{-1} \sin 0.5(M+1)\omega$  which is when  $\sin 0.5(M+1)\omega = -1$  i.e. when  $\omega = \frac{1.5\pi}{0.5(M+1)} = \frac{3\pi}{M+1}$ .

Hence  $\min W(e^{j\omega}) \approx \min 2\omega^{-1} \sin 0.5(M+1)\omega = -\frac{M+1}{1.5\pi}$ .

## Passband and Stopband ripple:

The ripple in  $W(e^{j\omega}) = \frac{\sin 0.5(M+1)\omega}{\sin 0.5\omega}$  has a period of  $\Delta\omega = \frac{2\pi}{0.5(M+1)} = \frac{4\pi}{M+1}$  and this gives rise to ripple with this period in both the passband and stopband of  $H_{M+1}(e^{j\omega})$ .

However the stopband ripple takes the value of  $H_{M+1}(e^{j\omega})$  alternately positive and negative. If you plot the magnitude response,  $|H_{M+1}(e^{j\omega})|$  then this ripple will be full-wave rectified and will double in frequency so its period will now be  $\frac{2\pi}{M+1}$ .

# Window relationships

When you multiply an impulse response by a window  $M + 1$  long

$$H_{M+1}(e^{j\omega}) = \frac{1}{2\pi} H(e^{j\omega}) \circledast W(e^{j\omega})$$

(a) passband gain  $\approx w[0]$ ; peak  $\approx \frac{w[0]}{2} + \frac{0.5}{2\pi} \int_{\text{mainlobe}} W(e^{j\omega}) d\omega$   
 rectangular window: passband gain = 1; peak gain = 1.09

(b) transition bandwidth,  $\Delta\omega$  = width of the main lobe  
 transition amplitude,  $\Delta H$  = integral of main lobe  $\div 2\pi$   
 rectangular window:  $\Delta\omega = \frac{4\pi}{M+1}$ ,  $\Delta H \approx 1.18$

(c) stopband gain is an integral over oscillating sidelobes of  $W(e^{j\omega})$   
 rect window:  $|\min H(e^{j\omega})| = 0.09 \ll |\min W(e^{j\omega})| = \frac{M+1}{1.5\pi}$

(d) features narrower than the main lobe will be broadened and attenuated

### Summary

### MATLAB routines

Rectangular:  $w[n] \equiv 1$

don't use

Hanning:  $0.5 + 0.5c_1$

$$c_k = \cos \frac{2\pi kn}{M+1}$$

rapid sidelobe decay

Hamming:  $0.54 + 0.46c_1$

best peak sidelobe

Blackman-Harris 3-term:

$$0.42 + 0.5c_1 + 0.08c_2$$

best peak sidelobe

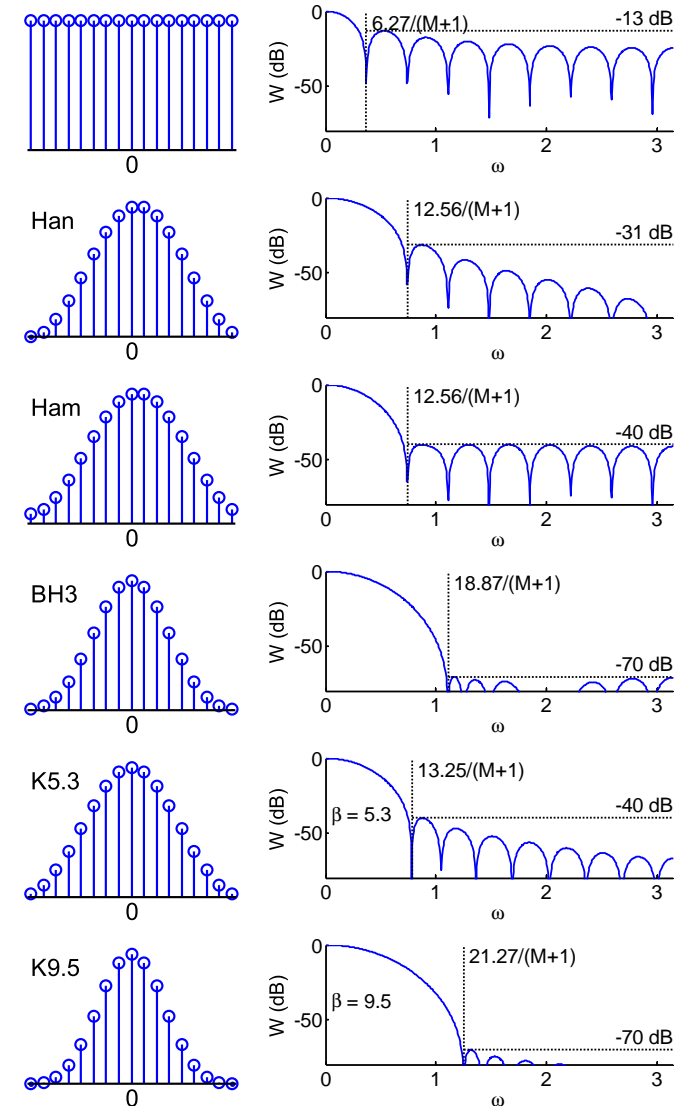

Kaiser:

$$\frac{I_0\left(\beta\sqrt{1-\left(\frac{2n}{M}\right)^2}\right)}{I_0(\beta)}$$

$\beta$  controls width v sidelobes

Good compromise:

Width v sidelobe v decay

# Order Estimation

## 6: Window Filter Design

### Inverse DTFT

### Rectangular window

### Dirichlet Kernel +

### Window relationships

### Common Windows

### ▷ Order Estimation

### Example Design

### Frequency sampling

### Summary

### MATLAB routines

Several formulae estimate the required order of a filter,  $M$ .

E.g. for lowpass filter

Estimated order is

$$M \approx \frac{-5.6 - 4.3 \log_{10}(\delta\epsilon)}{\omega_2 - \omega_1} \approx \frac{-8 - 20 \log_{10} \epsilon}{2.2 \Delta\omega}$$

Required  $M$  increases as either the transition width,  $\omega_2 - \omega_1$ , or the gain tolerances  $\delta$  and  $\epsilon$  get smaller.

Only approximate.

Example:

Transition band:  $f_1 = 1.8$  kHz,  $f_2 = 2.0$  kHz,  $f_s = 12$  kHz,

$$\omega_1 = \frac{2\pi f_1}{f_s} = 0.943, \quad \omega_2 = \frac{2\pi f_2}{f_s} = 1.047$$

Ripple:  $20 \log_{10}(1 + \delta) = 0.1$  dB,  $20 \log_{10} \epsilon = -35$  dB

$$\delta = 10^{\frac{0.1}{20}} - 1 = 0.0116, \quad \epsilon = 10^{\frac{-35}{20}} = 0.0178$$

$$M \approx \frac{-5.6 - 4.3 \log_{10}(2 \times 10^{-4})}{1.047 - 0.943} = \frac{10.25}{0.105} = 98 \quad \text{or} \quad \frac{35 - 8}{2.2 \Delta\omega} = 117$$

Summary

MATLAB routines

### Specifications:

Bandpass:  $\omega_1 = 0.5$ ,  $\omega_2 = 1$

Transition bandwidth:  $\Delta\omega = 0.1$

Ripple:  $\delta = \epsilon = 0.02$

$$20 \log_{10} \epsilon = -34 \text{ dB}$$

$$20 \log_{10} (1 + \delta) = 0.17 \text{ dB}$$

### Order:

$$M \approx \frac{-5.6 - 4.3 \log_{10}(\delta\epsilon)}{\omega_2 - \omega_1} = 92$$

### Ideal Impulse Response:

Difference of two lowpass filters

$$h[n] = \frac{\sin \omega_2 n}{\pi n} - \frac{\sin \omega_1 n}{\pi n}$$

### Kaiser Window: $\beta = 2.5$

Example Design

Frequency  
▷ sampling

Summary

MATLAB routines

Take  $M + 1$  uniform samples of  $H(e^{j\omega})$ ; take IDFT to obtain  $h[n]$

Advantage:

exact match at sample points

Disadvantage:

poor intermediate approximation if spectrum is varying rapidly

Solutions:

(1) make the filter transitions smooth over  $\Delta\omega$  width

(2) oversample and do least squares fit (can't use IDFT)

(3) use non-uniform points with more near transition (can't use IDFT)

# Summary

### Frequency sampling

### ▷ Summary

### MATLAB routines

- Make an FIR filter by windowing the IDTFT of the ideal response
  - Ideal lowpass has  $h[n] = \frac{\sin \omega_0 n}{\pi n}$
  - Add/subtract lowpass filters to make any piecewise constant response
- Ideal filter response is  $\otimes$  with the DTFT of the window
  - Rectangular window ( $W(z) = \text{Dirichlet kernel}$ ) has  $-13$  dB sidelobes and is always a bad idea
  - Hamming, Blackman-Harris are good
  - Kaiser good with  $\beta$  trading off main lobe width v. sidelobes
- Uncertainty principle: cannot be concentrated in both time and frequency
- Frequency sampling: IDFT of uniform frequency samples: not so great

For further details see Mitra: 7, 10.
